P8106 Data ScienceII Midterm

Yueran Zhang (yz4188)

2023-03-26

1. In this exercise, we will build tree-based models using the College data (see "College.csv" in Homework 2). The response variable is the out-of-state tuition (Outstate). Partition the dataset into two parts: training data (80%) and test data (20%).

```
library(tidyverse)
library(ISLR)
library(mlbench)
library(caret)
library(rpart)
library(rpart.plot)
library(party)
library(partykit)
library(pROC)
library(randomForest)
library(gbm)
library(pdp)
```

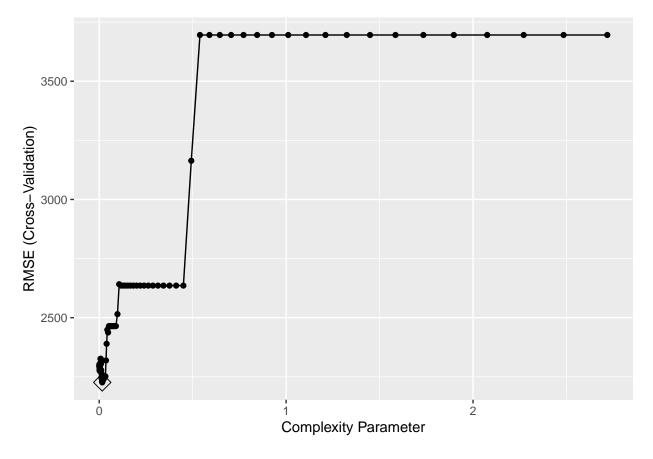

Import Dataset

```
# training data
x <- model.matrix(outstate ~. , training.data) [,-1]
y <- training.data$outstate

# test data
x2 <- model.matrix(outstate ~. , test.data)[,-1]
y2 <- test.data$outstate</pre>
```

Question A

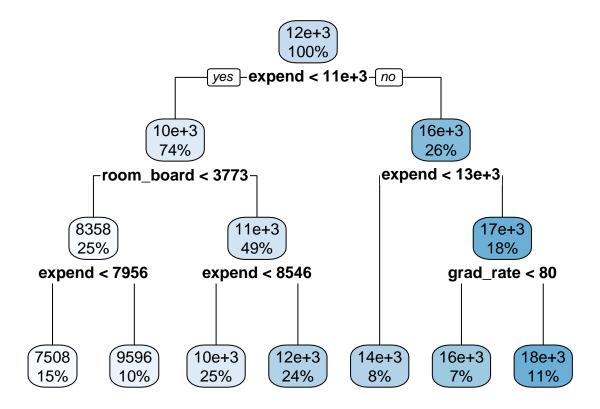

Build a regression tree on the training data to predict the response. Create a plot of the tree.

```
rpart.fit$bestTune
```

```
## cp
## 33 0.01618621
```

```
# Plot the tree
rpart.plot(rpart.fit$finalModel)
```

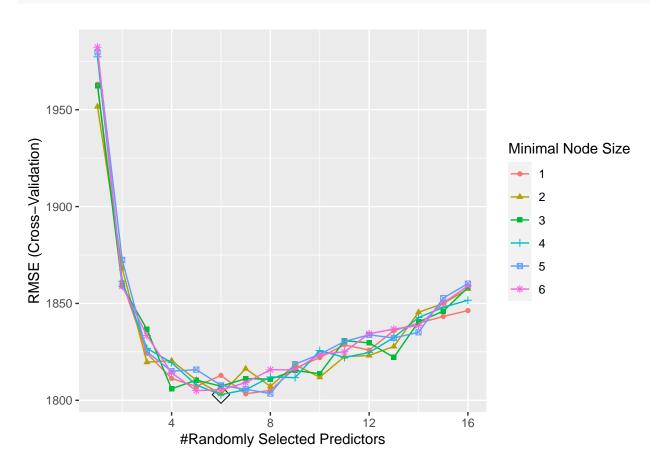

^{*} From the final model, we can report the best tuning parameter cp is 0.0161862120750658.

Question B

Perform random forest on the training data. Report the variable importance and the test error.

```
# Report the tuning parameter
ggplot(rf.fit, highlight = TRUE)
```

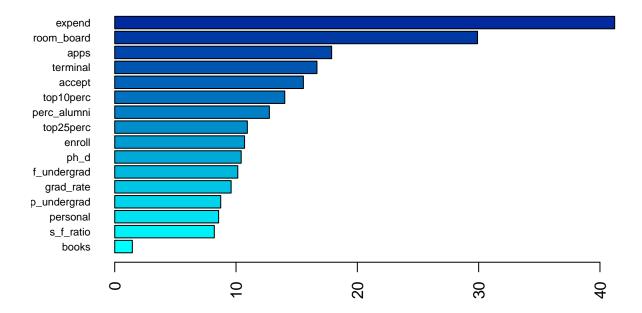

rf.fit\$bestTune

```
## mtry splitrule min.node.size
## 34 6 variance 4
```

• From the above output, ww can know that the best tuning parameters selected via CV are mtry = 6, splitrule = variance and min.node.size = 4.

```
las = 2, horiz = TRUE, cex.names = 0.7,
col = colorRampPalette(colors = c("cyan", "darkblue"))(19))
```

• We see that the variables expend(Instructional expenditure per student), Room_Board(Room and board costs) and apps(Number of applications received) are the top 3 from the variable importance.

```
set.seed(1234)

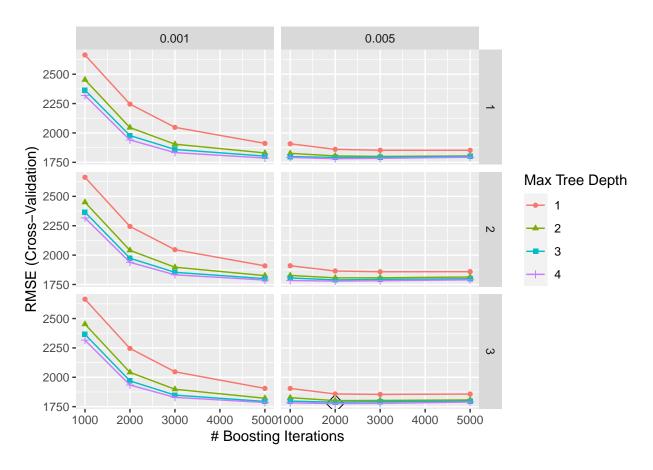

pred.rf <- predict(rf.fit, newdata = College[-RowTrain,])
test.error.rf <- RMSE(pred.rf, College$outstate[-RowTrain])
test.error.rf</pre>
```

[1] 1565.881

• The test error is 1565.880541.

Question C

Perform boosting on the training data. Report the variable importance and the test error.

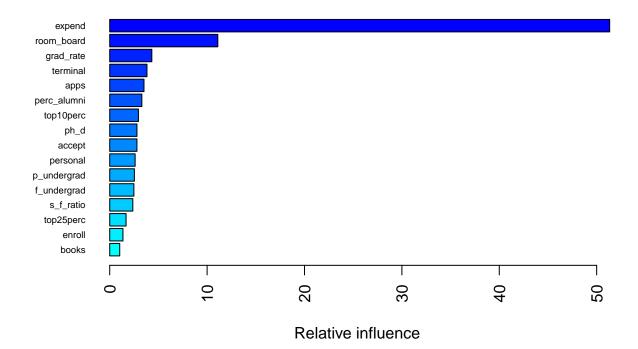

gbm.fit\$bestTune

```
## n.trees interaction.depth shrinkage n.minobsinnode ## 94 2000 4 0.005 3
```

• The best tuning parameters are n.trees = 2000, interaction.depth = 4, shrinkage = 0.005 and nminobsinode = 3.

```
set.seed(1234)
# Variable importance from boosting can be obtained using the `summary()` function.
summary(gbm.fit$finalModel, las = 2, cBars = 19, cex.names = 0.6)
```

```
##
                             rel.inf
                       var

                    enroll
                           1.357956
## books
                     books 1.027515
```

• We see that the variables expend(Instructional expenditure per student), Room_Board(Room and board costs) and grad_rate(Graduation rate) are the top 3 from the variable importance, which are slightly different from what we got from random forest model.

```
set.seed(1234)

pred.glm <- predict(gbm.fit, newdata = College[-RowTrain,])
test.error.glm <- RMSE(pred.glm, College$outstate[-RowTrain])
test.error.glm</pre>
```

[1] 1453.169

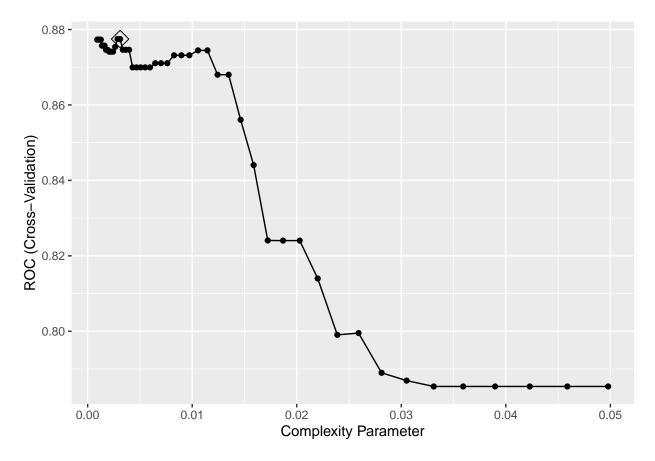

• The The test error is 1453.1694807.

2. This problem involves the OJ data in the ISLR package. The data contains 1070 purchases where the customers either purchased Citrus Hill or Minute Maid Orange Juice. A number of characteristics of customers and products are recorded. Create a training set containing a random sample of 700 observations, and a test set containing the remaining observations.

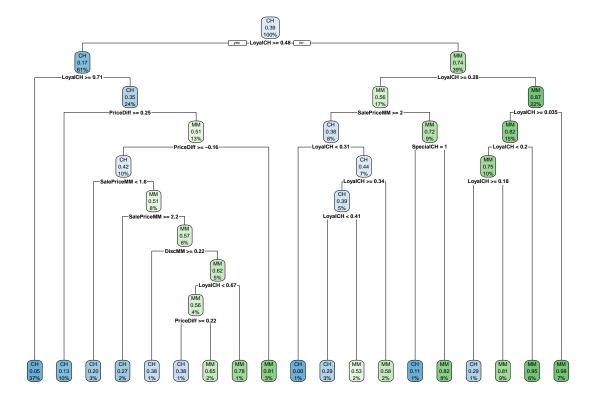

Question A

Build a classification tree using the training data, with Purchase as the response and the other variables as predictors. Which tree size corresponds to the lowest cross-validation error? Is this the same as the tree size obtained using the 1 SE rule?

We use Package caret to fit the classification tree, and plot with the final tree.

Tree plot with the lowest cross-validation error
rpart.plot(rpart.fit\$finalModel)

• From the above using lowest cross-validation error tree plot, the tree size is 19.

We use Package rpartfor 1SE rule.

```
##
## Classification tree:
## rpart(formula = Purchase ~ ., data = OJ, subset = RowTrain.OJ,
## control = rpart.control(cp = O))
##
## Variables actually used in tree construction:
```

```
## [1] DiscMM
